# Cellular Automata

- A 1D-CA  $\mathcal{A}$  is a tuple  $(\mathbb{Z}, S, \mathcal{N}, \delta)$ .

# Cellular Automata

- A 1D-CA  $\mathcal{A}$  is a tuple  $(\mathbb{Z}, S, \mathcal{N}, \delta)$ .

# Cellular Automata

- A 1D-CA  $\mathcal{A}$  is a tuple  $(\mathbb{Z}, S, \mathcal{N}, \delta)$ .

# Cellular Automata

- A 1D-CA  $\mathcal{A}$  is a tuple  $(\mathbb{Z}, S, \mathcal{N}, \delta)$ .

$$S = \{\square, \blacksquare\}$$

- A configuration  $C$  is a mapping from  $\mathbb{Z}$  to  $S$ .

# Cellular Automata

- A 1D-CA  $\mathcal{A}$  is a tuple  $(\mathbb{Z}, S, \mathcal{N}, \delta)$ .

$$S = \{\square, \blacksquare\}$$

$$\mathcal{N} \subseteq_{\text{finite}} \mathbb{Z}$$

- A configuration  $C$  is a mapping from  $\mathbb{Z}$  to  $S$ .

# Cellular Automata

- A 1D-CA  $\mathcal{A}$  is a tuple  $(\mathbb{Z}, S, \mathcal{N}, \delta)$ .

$$S = \{\square, \blacksquare\}$$

$$\delta : S^{|\mathcal{N}|} \rightarrow S$$

- A configuration  $C$  is a mapping from  $\mathbb{Z}$  to  $S$ .

# Cellular Automata

- A 1D-CA  $\mathcal{A}$  is a tuple  $(\mathbb{Z}, S, \mathcal{N}, \delta)$ .

$$S = \{\square, \blacksquare\}$$

- A configuration  $C$  is a mapping from  $\mathbb{Z}$  to  $S$ .

# Examples (1)

$$\sigma = (\mathbb{Z}, \{\blacksquare, \square\}, \{-1\}, q \mapsto q)$$

$$\Sigma_2 = (\mathbb{Z}, \{\blacksquare, \square\}, [-1, 0], (q, q') \mapsto q \oplus q'),$$

where  $(\{\blacksquare, \square\}, \oplus)$  is isomorphic to  $(\mathbb{Z}_2, +)$

# Examples (2)

$(\mathbb{Z}, \{\blacksquare, \square\}, \llbracket -1, 1 \rrbracket, \text{maj})$ ,  
where maj is majority between 3

$(\mathbb{Z}, \{\square, \blacksquare, \blacksquare, \blacksquare, \blacksquare, \blacksquare\}, \llbracket -1, 1 \rrbracket, \delta_6)$

# Computation Universality

**Idea.** A CA is *computation universal* if it can **compute** any partial recursive function.

# Computation Universality

**Idea.** A CA is *computation universal* if it can **compute** any partial recursive function.

- In practice : step-by-step Turing machine simulation.

A. R. Smith III. Simple Computation-Universal Cellular Spaces. 1971

# Universalities

**B. Durand and Z. Róka**, The game of life: universality revisited, *Cellular automata (Saissac, 1996)* (Kluwer Acad. Publ., Dordrecht, 1999), (pp. 51–74).

- Several different notions of universality :
  - Turing (computation universality) ;
  - Intrinsic (CA simulating all CA) ;
  - Circuits (CA simulating boolean circuits).
- Problems in the proof of universality of GOL.
- Discusses the difficulty of formalization.

# Inducing an Order on CA (1)

**Idea.** A CA  $\mathcal{A}$  is **less complex** than a CA  $\mathcal{B}$  if, up to some renaming of states and some rescaling, every space-time diagram of  $\mathcal{A}$  is a space-time diagram of  $\mathcal{B}$ .

# Inducing an Order on CA (1)

**Idea.** A CA  $\mathcal{A}$  is **less complex** than a CA  $\mathcal{B}$  if, up to some renaming of states and some rescaling, every space-time diagram of  $\mathcal{A}$  is a space-time diagram of  $\mathcal{B}$ .

**Definition.**  $\mathcal{A} \subseteq \mathcal{B}$  if there exists an injective mapping  $\varphi$  from  $S_{\mathcal{A}}$  into  $S_{\mathcal{B}}$  such that this diagram commutes :

$$\begin{array}{ccc} C & \xrightarrow{\varphi} & \overline{\varphi}(C) \\ G_{\mathcal{A}} \downarrow & & \downarrow G_{\mathcal{B}} \\ G_{\mathcal{A}}(C) & \xrightarrow{\varphi} & \overline{\varphi}(G_{\mathcal{A}}(C)) \end{array}$$

# Inducing an Order on CA (2)

**Definition.** The  $\langle m, n, k \rangle$  rescaling of  $\mathcal{A}$  is defined by :

$$G_{\mathcal{A}}^{\langle m, n, k \rangle} = \sigma^k \circ \circ^m \circ G_{\mathcal{A}}^n \circ \circ^{-m} .$$

$\mathcal{A}$

$\mathcal{A}^{\langle 4, 4, 1 \rangle}$

# Inducing an Order on CA (2)

**Definition.** The  $\langle m, n, k \rangle$  rescaling of  $\mathcal{A}$  is defined by :

$$G_{\mathcal{A}}^{\langle m, n, k \rangle} = \sigma^k \circ \circ^m \circ G_{\mathcal{A}}^n \circ \circ^{-m} .$$

$\mathcal{A}$

$\mathcal{A}^{\langle 4, 4, 1 \rangle}$

**Definition.**  $\mathcal{A} \leq \mathcal{B}$  if there exist  $\langle m, n, k \rangle$  and  $\langle m', n', k' \rangle$  such that  $\mathcal{A}^{\langle m, n, k \rangle} \subseteq \mathcal{B}^{\langle m', n', k' \rangle}$  .

# Inducing an Order on CA (3)

**Proposition.** The relation  $\leq$  is a quasi-order on CA.

- The induced order admits a maximal equivalence class.

**Definition.** A CA  $\mathcal{A}$  is *intrinsically universal* if :

$$\forall \mathcal{B}, \exists \langle m, n, k \rangle, \quad \mathcal{B} \subseteq \mathcal{A}^{\langle m, n, k \rangle} .$$

# Inducing an Order on CA (3)

**Proposition.** The relation  $\leq$  is a quasi-order on CA.

- The induced order admits a maximal equivalence class.

**Definition.** A CA  $\mathcal{A}$  is *intrinsically universal* if :

$$\forall \mathcal{B}, \exists \langle m, n, k \rangle, \quad \mathcal{B} \subseteq \mathcal{A}^{\langle m, n, k \rangle} .$$

**Proposition.** Every intrinsically universal CA is computation universal. **The converse is false.**

# Banks' Universal 2D-CA

$$\left( \mathbb{Z}^2, \{ \blacksquare, \square \}, \begin{array}{c} \text{---} \\ \text{---} \\ \text{---} \\ \text{---} \end{array}, \delta \right)$$

E. R. Banks. Universality in Cellular Automata. 1970

**Idea.** Emulate logical circuits by building :

- wires transporting binary signals
- logical gates AND, OR and NOT
- wires crossing

# Table of Content

1. Cellular Automata
2. Universalities
- 3. Rule 110 basics**
4. Cook-Wolfram proof

# Point of View

- We want to construct huge space-time diagrams.
- We need to prove their existence.
- We cannot simply draw some basis of them because of the size of diagrams involved (squares of millions of cells on a side).

# Tiling the plane

Space-time diagrams as tiling of the plane by triangles

Changing the point of view from 1D to 2D

# Particles

Particles repeats themselves  
in a uniform background

$$A = \left\langle \begin{pmatrix} 0 \\ 7 \end{pmatrix}, \cdot \begin{array}{c} \text{[particle shape]} \end{array} \right\rangle$$

$$B = \left\langle \begin{pmatrix} 0 \\ 7 \end{pmatrix}, \cdot \begin{array}{c} \text{[particle shape]} \end{array} \right\rangle$$

$$C = \left\langle \begin{pmatrix} 2 \\ 3 \end{pmatrix}, \cdot \begin{array}{c} \text{[particle shape]} \end{array} \right\rangle$$

# Collisions

Particles collide when meeting

$\Gamma : \begin{pmatrix} 0 \\ 0 \end{pmatrix} C + \begin{pmatrix} 0 \\ -4 \end{pmatrix} A \vdash \begin{pmatrix} 0 \\ 5 \end{pmatrix} B$   
+ some perturbation pattern F

We are given a set of valid elementary particles and elementary collisions

# Bindings

- To combine collisions we use one operation : binding.

$$\Gamma' = \left( \left( \begin{matrix} \alpha_1 \\ \beta_1 \end{matrix} \right) \Gamma_1 + \left( \begin{matrix} \alpha_2 \\ \beta_2 \end{matrix} \right) \Gamma_2 + \dots + \left( \begin{matrix} \alpha_n \\ \beta_n \end{matrix} \right) \Gamma_n \right)_{\text{bind}}$$

**Principle** Merge incoming and outgoing particles when possible. Some bindings are not valid !

- Binding is easy to construct and validate.

# Table of Content

1. Cellular Automata
2. Universalities
3. Rule 110 basics
- 4. Cook-Wolfram proof**

# Sketch of the proof

- We prove that rule 110 is Turing-universal.
  1. Reduce Turing Machines to Post Tag Systems.
  2. Reduce Tag Systems to Cyclic Tag Systems.
  3. Encode Cyclic Tag Systems with collisions.

# Post Tag Systems

**M. Minsky**, *Computation : Finite and Infinite Machines*  
(Prentice Hall, Englewoods Cliffs, 1967).

- A classical model used to prove universality of small Turing Machines.
- Configurations are words on  $\Sigma$ , a system is given by  $(k, v_1, \dots, v_{|\Sigma|})$ . A transition from  $u$  is done as follows :

$$u_1 \dots u_k u_{k+1} \dots u_m \vdash u_{k+1} \dots u_m \cdot v_{u_1}$$

- When the rule cannot be applied, the system accepts.

# Cyclic Tag systems

- A cyclic tag system acts only on the binary alphabet.
- A configuration is given by a word  $u$  and a set of finite words  $(v_1, \dots, v_n)$ .
- A transition is done as follows :
  1. if the first letter of  $u$  is 1 then concatenate  $v_1$  to  $u$  ;
  2. erase the first letter of  $u$  ;
  3. rotate the list of words as  $(v_2, \dots, v_n, v_1)$ .
- Such systems can simulate any Post Tag System.

# A Local Dynamical System

**Idea** Replace the finite set of words by a periodic one.

**Idea** Make the first letter cross the word letter by letter.

- A transition is done as follows :
  1. the first letter of  $u$  crosses the word to the right ;
  2. when it meets a boundary, it destroys it ;
  3. it begins either to erase or unfreeze letters ;
  4. when it meets the second boundary, it stops.

# A Sample CA

- 16 states, a large neighborhood  $(-1, 0, 1, 2)$ .
- Locally it can simulate the cyclic Tag system.

# A Sample CA

- 16 states, a large neighborhood  $(-1, 0, 1, 2)$ .
- Locally it can simulate the cyclic Tag system.

**Claim** This CA may not work ! Why ?

# A Sample CA

- 16 states, a large neighborhood  $(-1, 0, 1, 2)$ .
- Locally it can simulate the cyclic Tag system.

**Claim** This CA may not work! Why?

- Synchronization problems may appear. Be careful.

# Roadmap

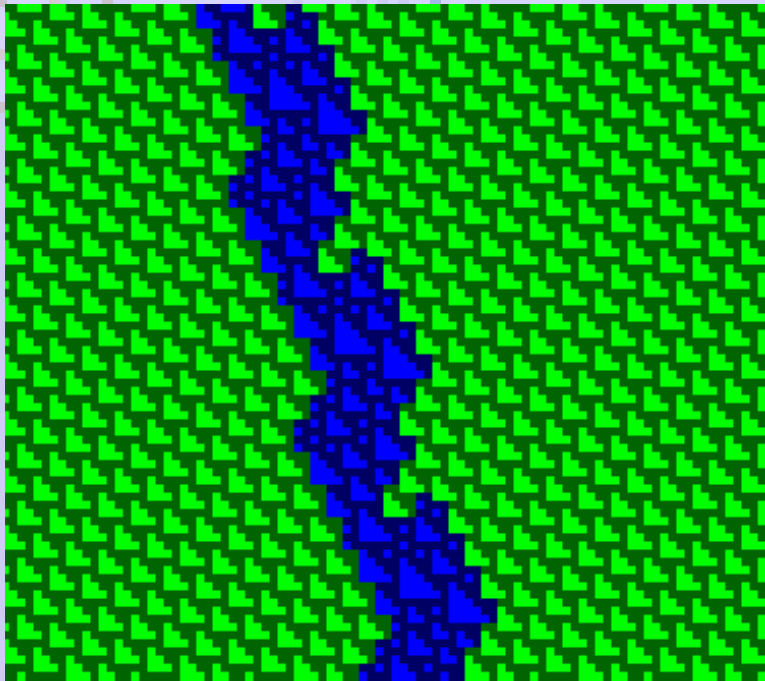

- Now we need to exhibit the gadgets for rule 110.
- This is very technical and requires an Oracle.
- M. Cook and S. Wolfram “tour de force”.

**S. Wolfram, *A New Kind of Science*, 2002**
